Unsupervised Visual Representation Learning by Context Prediction

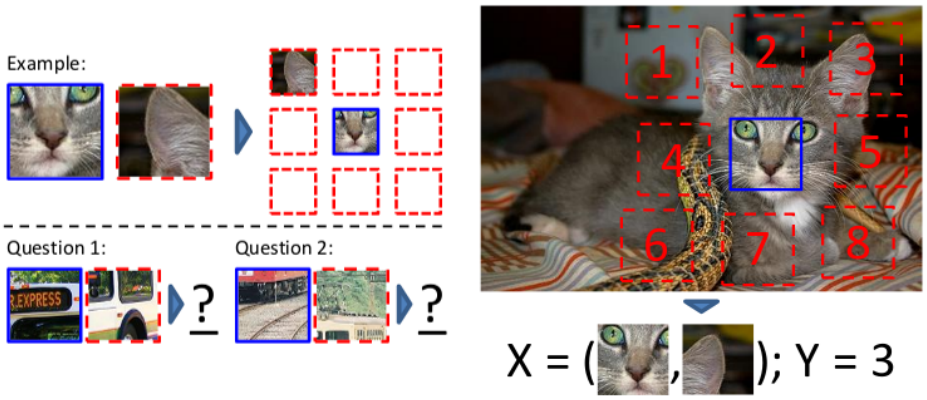
(2016)

Carl Doersch, Abhinav Gupta, Alexei A. Efros

Notes

Contributions

This paper explores context prediction as an unsupervised task for learning useful representation for other downstream tasks. Using randomly extracted pairs of patches, the training objective is to predict the position of the second patch relative to the first patch. More specifically, we sample random pairs of patches and present them to each pair as a training examples, the model must predict the correct position of one patch given the position of the other patch without any additionnal information about their positions in the original image.



The authors argue that by training on this simple task, the learned representations allow us to perform unsupervised visual discovery, or even use this model as a starting point for other visual tasks instead of using a randomly initialized model, which gives better results without the need for labeled examples.

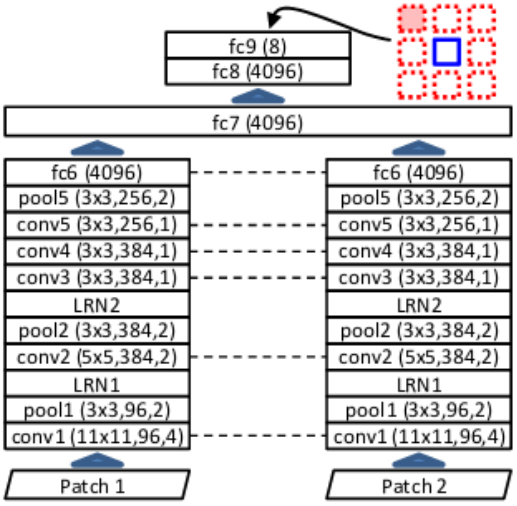
Visual Context Prediction

When choosing a given task, we must ensure that the task enforce the model to learn useful representations and not simply taking shortcuts to get to the correct prediction.

In our case, we must not boundary patterns or texture continuity is obvious. To avoid this the patches are selected with pair wise distances up to 0.5 of the size of each patch, with an additionnal jittering of the positiong up to 7 pixels, one aditionnal thing the authors observed the network uses to cheat is the Chromatic aberration, in some cameras one color channel is focused tward the center the model uses to localize the patches to the lens itself and find their relative positions, to overcome this the authors propsoe to randomly drop 2 of the 3 color channels.

After contructing a training dataset as a set of pairs $(patch_1, patch_2)$ as inputs, and the position of the second pair relative to the first as targets, we can use and CNN similar to AlexNet for training,

we must feed the two patches into the network, concatenate the two output into one 4096 vector, and use two fully connected layers to output a probability distribution over the 8 possible positions.



Experiments

Pre-training We can use our self-supervised task to pretrain a model for a given visual taskn object detection in our case, and we see competitive results compared to pretraining using ImageNet:

Table 1. Mean Average Precision on VOC-2007.

Nearest Neighbors To check if similar patches do indeed have similar representations, we can randomly sample a given number of 96 x 96 patches, and represent them using the FC6 features, and for a given patch, we find the nearest neighbors based on the FC6 features using a normalized correlation, the results are in the figure bellow:
